

API

An application programming interface (API) is a connection between [computers](#) or between [computer programs](#). It is a type of software [interface](#), offering a service to other pieces of [software](#).^[1] A document or standard that describes how to build such a connection or interface is called an API specification. A computer system that meets this standard is said to implement or expose an API. The term API may refer either to the specification or to the implementation

In contrast to a [user interface](#), which connects a computer to a person, an application programming interface connects computers or pieces of software to each other. It is not intended to be used directly by a person (the [end user](#)) other than a [computer programmer](#) who is incorporating it into software. An API is often made up of different parts which act as tools or services that are available to the programmer. A program or a programmer that uses one of these parts is said to call that portion of the API. The calls that make up the API are also known as [subroutines](#), methods, requests, or [endpoints](#). An API specification defines these calls, meaning that it explains how to use or implement them. One purpose of APIs is to [hide the internal details](#) of how a system works, exposing only those parts a programmer will find useful and keeping them consistent even if the internal details later change. An API may be custom-built for a particular pair of systems, or it may be a shared standard allowing [interoperability](#) among many systems.

The term API is often used to refer to [web APIs](#),^[2] which allow communication between computers that are joined by the [internet](#). There are also APIs for [programming languages](#), [software libraries](#), computer [operating systems](#), and [computer hardware](#). APIs originated in the 1940s, though the term did not emerge until the 1960s and 70s
